Current					
+15V			8	11	mA
-15V			-12	-20	mA
+5V			4.5	8	mA

## NOTES:

1. Absolute maximum ratings are limiting values, applied individually, beyond which the serviceability of the circuit may be impaired. Functional operation under any of these conditions is not necessarily implied.
2. Adjustable to zero using external potentiometers.
3. See definitions.
4. FSR is "Full Scale Range" and is 20V for ±10V range, 10V for ±5V range, etc., or 2mA (±20%) for current output.
5. The HI-5680 will operate with supply voltages as low as ±11.4V. It is recommended that output voltage range -10V to +10V not be used if the supply voltages are less than ±12V.
6. With gain and offset errors adjusted to zero at 25°C.

**Die Characteristics**

Transistor Count	259
Die Size:	210 x 125 mils
Thermal Constants; $\theta_{ja}$	49°C/W
$\theta_{jc}$	12°C/W
Tie Substrate to:	Ground
Process:	Bipolar - DI

## Definitions of Specifications

### DIGITAL INPUTS

The HI-5680 accepts digital input codes in complementary binary, complementary offset binary, and complementary two's complement binary.

DIGITAL INPUT	ANALOG OUTPUT		
	Complementary Binary	Complementary Offset Binary	Complementary Two's Complement*
MSB LSB			-LSB
000...000	+ Full Scale	+ Full Scale	+ Full Scale
100...000	Mid Scale -1 LSB	-1 LSB	Zero
111...111	Zero	- Full Scale	- Full Scale
011...111	+½ Full Scale	Zero	- Full Scale

\* Invert MSB with external inverter to obtain CTC Coding

### SETTLING TIME

That interval between application of a digital step input, and final entry of the analog output within a specified window about the settled value. Harris Semiconductor usually specifies a unipolar 10V or bipolar full scale step, to be measured from 50% of the input digital transition, and a window of  $\pm\frac{1}{2}$  LSB about the final value. The device output is then rated according to the worst (longest settling) case: low to high, or high to low.

### DRIFT

**GAIN DRIFT** – The change in full scale analog output over the specified temperature range expressed in parts per million of full scale per °C (ppm of FSR/°C). Gain error is measured with respect to +25°C at high ( $T_H$ ) and low ( $T_L$ ) temperatures. Gain drift is calculated for both high ( $T_H$  – 25°C) and low ranges (+25°C –  $T_L$ ) by dividing the gain error by the respective change in temperature. The specification is the larger of the two representing worst case drift.

**OFFSET DRIFT** – The change in analog output with all bits = OFF over the specified temperature range expressed in parts per million of full scale range per °C (ppm of FSR/°C). Offset error is measured with respect to +25°C at high ( $T_H$ ) and low ( $T_L$ ) temperatures. Offset Drift is calculated for both high ( $T_H$  – 25°C) and low (+25°C –  $T_L$ ) ranges by dividing the offset error by the respective change in temperature. The specification given is the larger of the two, representing worst-case drift.

### ACCURACY

**INTEGRAL NONLINEARITY** – The maximum deviation of the actual transfer characteristic from an ideal straight line. The ideal line is positioned according to "end-point linearity" for D/A converter products from Harris Semiconductor, i.e. the line is drawn between the end-points of the actual transfer characteristic (codes 00...0 and 11...1).

**DIFFERENTIAL NONLINEARITY** – The difference between one LSB and the output voltage change corresponding to any two consecutive codes. A Differential Nonlinearity of  $\pm 1$  LSB or less guarantees monotonicity.

**MONOTONICITY** – The property of a D/A converter's transfer function which guarantees that the output derivative will not change sign in response to a sequence of increasing (or decreasing) input codes. That is, the only output response to a code change is to remain constant, increase for increasing code, or decrease for decreasing code.

### POWER SUPPLY SENSITIVITY

Power Supply Sensitivity is a measure of the change in gain and offset of the D/A converter resulting from a change in -15V, or +15V supplies. It is specified under DC conditions and expressed as parts per million of full scale range per percent of change in power supply (ppm of FSR%).

### COMPLIANCE

Compliance Voltage is the maximum output voltage range that can be tolerated and still maintain its specified accuracy. Compliance Limit implies functional operation only and makes no claims to accuracy.

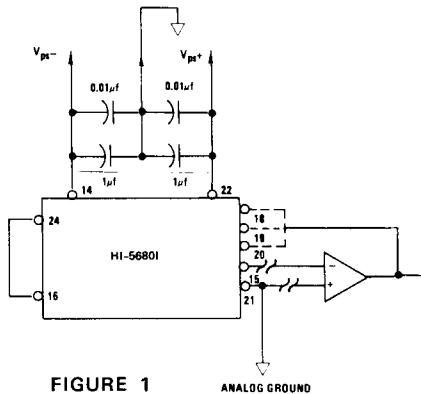

### GLITCH

A glitch on the output of a D/A converter is a transient spike resulting from unequal internal ON-OFF switching times. Worst case glitches usually occur at half-scale or the major carry code transition from 011...1 to 100...0 or vice versa. For example, if turn ON is greater than turn OFF for 011...1 to 100...0, an intermediate state of 000...0 exists, such that the output momentarily glitches toward zero output. Matched switching times and fast switching will reduce glitches considerably. (Measured as one half the product of duration and amplitude.)

# Operating Instructions

## DECOUPLING AND GROUNDING

For best accuracy and high frequency performance, the grounding and decoupling scheme shown in Figure 1 should be used. Decoupling capacitors should be connected close to the HI-5680 (preferably to the device pins) and should be tantalum or electrolytic bypassed with ceramic types for best high frequency noise rejection.

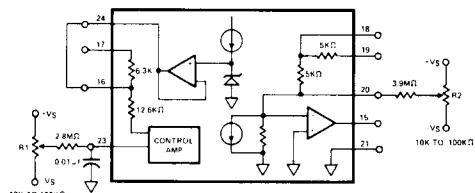

**FIGURE 1**

## REFERENCE SUPPLY

An internal 6.3 Volt reference is provided on board all HI-5680 models. This voltage (pin 24) is accurate to  $\pm 2\%$  and must be connected to the reference input (pin 16) for specified operation. This reference may be used externally, provided current drain is limited to 2.5mA. An external buffer amplifier is recommended if this reference is to be used to drive other system components. Otherwise, variations in the load driven by the reference will result in gain variations of the HI-5680. All gain adjustments should be made under constant load conditions.

## VOLTAGE OUTPUT HI-5680V

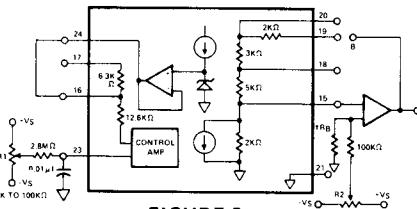

**FIGURE 2**

## RANGE CONNECTIONS

	RANGE	CONNECT		
		PIN 15	PIN 17	PIN 19
Unipolar	0 to +5V	18	N.C.	20
	0 to +10V	18	N.C.	N.C.
Bipolar	$\pm 2.5V$	18	20	20
	$\pm 5V$	18	20	N.C.
	$\pm 10V$	19	20	15

## CURRENT OUTPUT HI-5680I

**FIGURE 3**

$\dagger R_B$  should equal the DAC's output resistance, which is  $2K\Omega // R_{FEEDBACK}$ .

## EXTERNAL AMPLIFIER CONNECTIONS

To use the HI-5680I with an external amplifier, connect as follows:

RANGE	PIN 17 to	PIN 18 to	PIN 19 to	PIN 20 to
0 to +10V	N.C.	B	18*	19*
0 to +5V	N.C.	B	15	N.C.
$\pm 10V$	15	N.C.	B	N.C.
$\pm 5V$	15	B	18*	19*
$\pm 2.5V$	15	B	15	N.C.

\*these connections help reduce stray capacitance in the feedback loop.

## GAIN AND OFFSET CALIBRATION

(Applies to Figure 2 and 3.)

### UNIPOLAR CALIBRATION

#### Step 1: Offset

Turn all bits OFF (11...1)  
Adjust  $R_2$  for zero volts out

#### Step 2: Gain

Turn all bits ON (00...0)  
Adjust  $R_1$  for FS-1LSB  
That is:  
 $4.9988$  for 0 to +5V range  
 $9.9976$  for 0 to +10V range

### BIPOLAR CALIBRATION

#### Step 1: Offset

Turn all bits OFF (11...1)  
Adjust  $R_2$  for Negative FS  
That is:  
 $-10V$  for  $\pm 10V$  range  
 $-5V$  for  $\pm 5V$  range  
 $-2.5V$  for  $\pm 2.5V$  range

#### Step 2: Gain

Turn all bits ON (00...0)  
Adjust  $R_1$  for positive FS-1LSB  
That is:  
 $+9.9951V$  for  $\pm 10V$  range  
 $+4.9976V$  for  $\pm 5V$  range  
 $+2.4988V$  for  $\pm 2.5V$  range

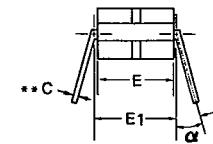

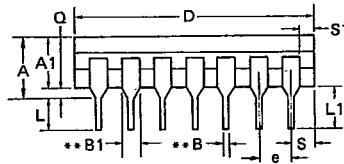

This Bipolar procedure adjusts the output range end points. The maximum error at zero (half scale) will not exceed the Linearity error. See the "Accuracy" specifications.
