HEF4750V LSI

DESCRIPTION

The HEF4750V frequency synthesizer is one of a pair of LOCMOS devices, primarily intended for use in high-performance frequency synthesizers, e.g. in all communication, instrumentation, television and broadcast applications. A combination of analogue and digital techniques results in an integrated circuit that enables high performance. The complementary device is the universal divider type HEF4751V.

Together with a standard prescaler, the two LOCMOS integrated circuits offer low-cost single loop synthesizers with full professional performance. Salient features offered (in combination with HEF4751V) are:

- Wide choice of reference frequency using a single crystal.
- High-performance phase comparator low phase noise low spurii.
- System operation to > 1 GHz.
- Typical 15 MHz input at 10 V.
- · Flexible programming:

frequency offsets

ROM compatible

fractional channel capability.

- Programme range 6½ decades, including up to 3 decades of prescaler control.
- · Division range extension by cascading.
- Built-in phase modulator.
- · Fast lock feature.
- · Out-of-lock indication.
- · Low power dissipation and high noise immunity.

APPLICATION INFORMATION

Some examples of applications for the HEF4750V in combination with the HEF4751V are:

- VHF/UHF mobile radios.
- · HF s.s.b. transceivers.
- · Airborne and marine communications and navaids.
- · Broadcast transmitters.
- · High quality radio and television receivers.
- · High performance citizens band equipment.
- · Signal generators.

Fig.2 Block diagram comprising five basic functions: phase comparator 1 (PC1), phase comparator 2 (PC2), phase modulator, reference oscillator and reference divider. These functions are described separately.

HEF4750V LSI

FUNCTIONAL DESCRIPTION

Phase comparator 1

Phase comparator 1 (PC1) is built around a SAMPLE and HOLD circuit. A negative-going transition at the V-input causes the hold capacitor (C_A) to be discharged and after a specified delay, caused by the Phase Modulator by means of an internal V' pulse, it produces a positive-going ramp. A negative-going transition at the R-input terminates

the ramp. Capacitor C_A holds the voltage that the ramp has attained. Via an internal sampling switch this voltage is transferred to C_C and in turn buffered and made available at output PC_1 .

If the ramp terminates before an R-input is present, an internal end of ramp (EOR) signal is produced.

These actions are illustrated in Fig.3.

The resultant phase characteristic is shown in Fig.4.

HEF4750V LSI

PC1 is designed to have a high gain, typically 3200 V/cycle (at 12,5 kHz). This enables a low noise performance.

Phase comparator 2

Phase comparator 2 (PC2) has a wide range, which enables faster lock times to be achieved than otherwise would be possible. It has a linear \pm 360° phase range, which corresponds to a gain of typically 5 V/cycle.

This digital phase comparator has three stable states:

- · reset state,
- · V' leads R state,
- R leads V' state.

Conversion from one state to another takes place according to the state diagram of Fig.5.

Output PC_2 produces positive or negative-going pulses with variable width; they depend on the phase relationship of R and V'. The average output voltage is a linear function of the phase difference. Output PC_2 remains in the high impedance OFF-state in the region in which PC1 operates. The resultant phase characteristic is shown in Fig.6.

HEF4750V LSI

Strobe function

The strobe function is intended for applications requiring extremely fast lock times. In normal operation the additional strobe input (STB) can be connected to the V-input and the circuit will function as described in the previous sections.

In single, phase-locked-loop type frequency synthesizers, the comparison frequency generally used is either the nominal channel spacing or a sub-multiple. PC2 runs at the higher frequency (a higher reference frequency must also be used), whilst strobing takes place on the lower frequency, thereby obtaining a decrease in lock time. In a system using the Universal Divider HEF4751V, the output OFS cycles on the lower frequency, the output OFF cycles on the higher frequency.

Out-of-lock function

There are a number of situations in which the system goes from the locked to the out-of-lock state (OL goes HIGH):

- 1. When V' leads R, however out of the range of PC1.
- 2. When R leads V'.
- 3. When an R-pulse is missing.
- 4. When a V-pulse is missing.
- 5. When two successive STB-commands occur, the first without corresponding V-signal.

Phase modulator

The phase modulator only uses one external capacitor, C_B at pin TCB. A negative-going transition at the V-input causes C_B to produce a positive-going linear ramp. When the ramp has reached a value almost equal to the modulation input voltage (at MOD), the ramp terminates, C_B discharges and a start signal to the C_A -ramp at TCA is produced. A linear phase modulation is reached in this

way. If no modulation is required, the MOD-input must be connected to a fixed voltage of a certain positive value up to V_{DD} . Care must be taken that the V' pulse is never smaller than the minimum value to ensure that the external capacitor of PC1 (C_A) can be discharged during that time. Since the V' pulse width is directly related to the TCB ramp duration, there is a requirement for the minimum value of this ramp duration.

Reference oscillator

The reference oscillator normally operates with an external crystal as shown in Fig.2. The internal circuitry can be used as a buffer amplifier in case an external reference should be required.

Reference divider

The reference divider consists of a binary divider with a programmable division ratio of 1 to 1024 and a prescaler with selectable division ratios of 1, 2, 10 and 100, according to the following tables:

Binary divider

| N (A ₀ TO A ₉) | DIVISION RATIO |
|---------------------------------------|----------------|
| 0 | 1024 |
| $0 \le N \le 1023$ | N |

Prescaler

| PROGRAMMING WORD (NS ₀ , NS ₁) | DIVISION RATIO |
|---|----------------|
| 0 | 1 |
| 1 | 2 |
| 2 | 10 |
| 3 | 100 |

Frequency synthesizer

HEF4750V LSI

In this way suitable comparison frequencies can be obtained from a range of crystal frequencies. The divider can also be used as a 'stand alone' programmable divider by connecting input TRA to V_{DD} , which causes all internal analogue currents to be switched off.

Biasing circuitry

The biasing circuitry uses an external current source or resistor, which has to be connected between the TRA and V_{SS} pins. This circuitry supplies all analogue parts of the circuit. Consequently the analogue properties of the device, such as gain, charge currents, speed, power dissipation, impedance levels etc., are mainly determined by the value of the input current at TRA. The TRA input must be decoupled to V_{DD} , as shown in Fig.7. The value of C_D has to be chosen such that the TRA input is 'clean', e.g. 10 nF at $R_A=68\ k\Omega$.

RATINGS

Limiting values in accordance with the Absolute Maximum System (IEC 134)

| Supply voltage | V_{DD} | -0,5 t | to + 15 V |
|---------------------------------------|-----------|--------------------|--------------------|
| Voltage on any input | V_{I} | $-0,5$ to V_{DI} | $_{\rm D}$ + 0,5 V |
| D.C. current into any input or output | ±Ι | max. | 10 mA |
| Power dissipation per package | | | |
| for $T_{amb} = 0$ to $+ 85$ °C | P_{tot} | max. | 500 mW |
| Power dissipation per output | | | |
| for T _{amb} = 0 to 85 °C | Р | max. | 100 mW |
| Storage temperature | T_{stg} | −65 to | + 150 °C |
